Problem Statement

Continuous Domain Search/Optimization

 Task: minimize an objective function (fitness function, loss function) in continuous domain

$$f: \mathcal{X} \subseteq \mathbb{R}^n \to \mathbb{R}, \qquad \mathbf{x} \mapsto f(\mathbf{x})$$

Black Box scenario (direct search scenario)

- gradients are not available or not useful
- problem domain specific knowledge is used only within the black box, e.g. within an appropriate encoding
- Search costs: number of function evaluations

Problem Statement

Continuous Domain Search/Optimization

- Goal
 - fast convergence to the global optimum
 - ... or to a robust solution x os solution x with small function value f(x) with least search cost

there are two conflicting objectives

- Typical Examples
 - shape optimization (e.g. using CFD)
 - model calibration
 - parameter calibration

curve fitting, airfoils biological, physical

controller, plants, images

- Problems
 - exhaustive search is infeasible
 - naive random search takes too long
 - deterministic search is not successful / takes too long

Approach: stochastic search, Evolutionary Algorithms

Objective Function Properties

We assume $f:\mathcal{X}\subset\mathbb{R}^n\to\mathbb{R}$ to be *non-linear, non-separable* and to have at least moderate dimensionality, say $n\not\ll 10$. Additionally, f can be

- non-convex
- multimodal

there are possibly many local optima

non-smooth

derivatives do not exist

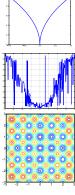

- discontinuous
- ill-conditioned
- noisy
- ...

Goal: cope with any of these function properties
they are related to real-world problems

What Makes a Function Difficult to Solve?

Why stochastic search?

- non-linear, non-quadratic, non-convex on linear and quadratic functions much better search policies are available
- ruggedness non-smooth, discontinuous, multimodal, and/or noisy function
- dimensionality (size of search space)
 (considerably) larger than three
- non-separability
 dependencies between the objective variables
- ill-conditioning

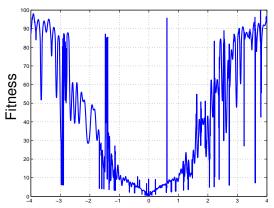

gradient direction Newton direction

Ruggedness

non-smooth, discontinuous, multimodal, and/or noisy

cut from a 5-D example, (easily) solvable with evolution strategies

Curse of Dimensionality

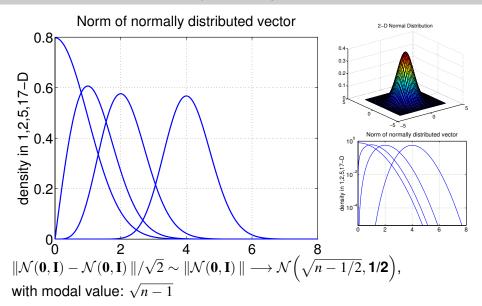

The term *Curse of dimensionality* (Richard Bellman) refers to problems caused by the **rapid increase in volume** associated with adding extra dimensions to a (mathematical) space.

Example: Consider placing 100 points onto a real interval, say [0,1]. To get **similar coverage**, in terms of distance between adjacent points, of the 10-dimensional space $[0,1]^{10}$ would require $100^{10}=10^{20}$ points. A 100 points appear now as isolated points in a vast empty space.

Remark: **distance measures** break down in higher dimensionalities (the central limit theorem kicks in)

Consequently, a **search policy** (e.g. exhaustive search) that is valuable in small dimensions **might be useless** in moderate or large dimensional search spaces.

Effect of Dimensionality: Example

Separable Problems

Definition (Separable Problem)

A function f is separable if

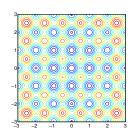

$$\arg\min_{(x_1,\ldots,x_n)} f(x_1,\ldots,x_n) = \left(\arg\min_{x_1} f(x_1,\ldots),\ldots,\arg\min_{x_n} f(\ldots,x_n)\right)$$

 \Rightarrow it follows that f can be optimized in a sequence of n independent 1-D optimization processes

Example: Additively decomposable functions

$$f(x_1,\dots,x_n) = \sum_{i=1}^n f_i(x_i)$$

Rastrigin function

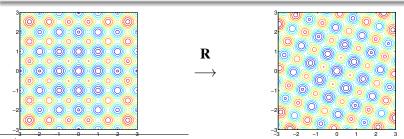

Non-Separable Problems

Building a non-separable problem from a separable one (1,2)

Rotating the coordinate system

- $f: x \mapsto f(x)$ separable
- $\bullet f: x \mapsto f(\mathbf{R}x)$ non-separable

R rotation matrix

² Salomon (1996). "Reevaluating Genetic Algorithm Performance under Coordinate Rotation of Benchmark Functions; A survey of some theoretical and practical aspects of genetic algorithms." BioSystems, 39(3):263-278

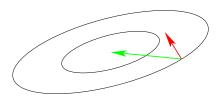

III-Conditioned Problems

Curvature of level sets

Consider the convex-quadratic function

$$f(\mathbf{x}) = \frac{1}{2}(\mathbf{x} - \mathbf{x}^*)^T \mathbf{H}(\mathbf{x} - \mathbf{x}^*) = \frac{1}{2} \sum_i h_{i,i} x_i^2 + \frac{1}{2} \sum_{i \neq j} h_{i,j} x_i x_j$$

$$\mathbf{H} \text{ is Hessian matrix of } f \text{ and symmetric positive definite}$$

gradient direction $-f'(x)^{T}$

Newton direction $-\mathbf{H}^{-1}f'(\mathbf{x})^{\mathrm{T}}$

Ill-conditioning means **squeezed level sets** (high curvature). Condition number equals nine here. Condition numbers up to 10^{10} are not unusual in real world problems.

If $H \approx I$ (small condition number of H) first order information (e.g. the gradient) is sufficient. Otherwise **second order information** (estimation of H^{-1}) is **necessary**.

What Makes a Function Difficult to Solve?

... and what can be done

The Problem	The Approach in ESs and continuous EDAs
Dimensionality, Non-Separability	exploiting the problem structure locality, neighborhood, encoding
III-conditioning	second order approach changes the neighborhood metric
Ruggedness	non-local policy, large sampling width (step-size) as large as possible while preserving a reasonable convergence speed
	stochastic, non-elitistic, population-based method
	recombination operator serves as repair mechanism
	restarts

Stochastic Search

A black box search template to minimize $f: \mathbb{R}^n \to \mathbb{R}$

Initialize distribution parameters θ , set population size $\lambda \in \mathbb{N}$ While not terminate

- ① Sample distribution $P(x|\theta) o x_1, \dots, x_\lambda \in \mathbb{R}^n$
- 2 Evaluate x_1, \ldots, x_{λ} on f
- **3** Update parameters $\theta \leftarrow F_{\theta}(\theta, x_1, \dots, x_{\lambda}, f(x_1), \dots, f(x_{\lambda}))$

Everything depends on the definition of P and F_{θ}

deterministic algorithms are covered as well

16/80

In many Evolutionary Algorithms the distribution P is implicitly defined via **operators on a population**, in particular, selection, recombination and mutation

Natural template for Estimation of Distribution Algorithms

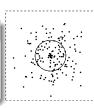

Evolution Strategies

New search points are sampled normally distributed

$$x_i \sim m + \sigma \mathcal{N}_i(\mathbf{0}, \mathbf{C})$$
 for $i = 1, \dots, \lambda$

for
$$i = 1, \ldots, \lambda$$

as perturbations of m, where $x_i, m \in \mathbb{R}^n$, $\sigma \in \mathbb{R}_+$, $\mathbf{C} \in \mathbb{R}^{n \times n}$

where

- the mean vector $\mathbf{m} \in \mathbb{R}^n$ represents the favorite solution
- the so-called step-size $\sigma \in \mathbb{R}_+$ controls the step length
- the covariance matrix $C \in \mathbb{R}^{n \times n}$ determines the **shape** of the distribution ellipsoid

here, all new points are sampled with the same parameters

The question remains how to update m, \mathbb{C} , and σ .

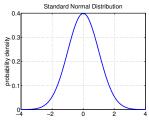

Why Normal Distributions?

- widely observed in nature, for example as phenotypic traits
- only stable distribution with finite variance stable means the sum of normal variates is again normal, helpful in design and analysis of algorithms
- most convenient way to generate **isotropic** search points
 the isotropic distribution does **not favor any direction**
- maximum entropy distribution with finite variance
 the least possible assumptions on f in the distribution shape

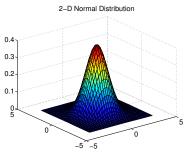

connection to central limit theorem

(unfoundedly), supports rotational invariance

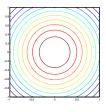

Normal Distribution

probability density of the 1-D standard normal distribution

probability density of a 2-D normal distribution

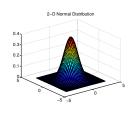

The Multi-Variate (*n*-Dimensional) Normal Distribution

Any multi-variate normal distribution $\mathcal{N}(m, \mathbb{C})$ is uniquely determined by its mean value $m \in \mathbb{R}^n$ and its symmetric positive definite $n \times n$ covariance matrix \mathbb{C} .

The **mean** value *m*

- determines the displacement (translation)
- value with the largest density (modal value)
- the distribution is symmetric about the distribution mean

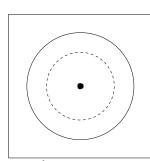

The covariance matrix C

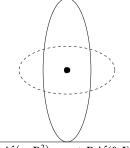

- determines the shape
- **geometrical interpretation**: any covariance matrix can be uniquely identified with the iso-density ellipsoid $\{x \in \mathbb{R}^n \mid (x-m)^T \mathbb{C}^{-1}(x-m) = 1\}$

... any **covariance matrix** can be uniquely identified with the iso-density ellipsoid $\{x \in \mathbb{R}^n \mid (x - m)^T \mathbf{C}^{-1} (x - m) = 1\}$

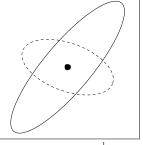

Lines of Equal Density

 $\mathcal{N}(\mathbf{m}, \sigma^2 \mathbf{I}) \sim \mathbf{m} + \sigma \mathcal{N}(\mathbf{0}, \mathbf{I})$ one degree of freedom σ components are independent standard normally distributed

 $\mathcal{N}\left(m,\mathbf{D}^2\right)\sim m+\mathbf{D}\,\mathcal{N}(\mathbf{0},\mathbf{I})$ n degrees of freedom components are independent, scaled

 $\mathcal{N}(m,\mathbf{C}) \sim m + \mathbf{C}^{\frac{1}{2}} \mathcal{N}(\mathbf{0},\mathbf{I})$ $(n^2+n)/2$ degrees of freedom components are correlated

where I is the identity matrix (isotropic case) and D is a diagonal matrix (reasonable for separable problems) and $A \times \mathcal{N}(0,I) \sim \mathcal{N}(0,AA^T)$ holds for all A.

Evolution Strategies

Terminology

Let μ : # of parents, λ : # of offspring

Plus (elitist) and comma (non-elitist) selection

$$(\mu + \lambda)$$
-ES: selection in {parents} \cup {offspring} (μ, λ) -ES: selection in {offspring}

$$(1+1)$$
-ES

Sample one offspring from parent *m*

$$\mathbf{x} = \mathbf{m} + \sigma \, \mathcal{N}(\mathbf{0}, \mathbf{C})$$

If x better than m select

$$m \leftarrow x$$

The $(\mu/\mu, \lambda)$ -ES

Non-elitist selection and intermediate (weighted) recombination

Given the *i*-th solution point
$$x_i = m + \sigma \underbrace{\mathcal{N}_i(\mathbf{0}, \mathbf{C})}_{=:y_i} = m + \sigma y_i$$

Let $x_{i:\lambda}$ the *i*-th ranked solution point, such that $f(x_{1:\lambda}) \leq \cdots \leq f(x_{\lambda:\lambda})$. The new mean reads

$$m \leftarrow \sum_{i=1}^{\mu} w_i \mathbf{x}_{i:\lambda} = m + \sigma \underbrace{\sum_{i=1}^{\mu} w_i \mathbf{y}_{i:\lambda}}_{=: \mathbf{y}_w}$$

where

$$w_1 \ge \dots \ge w_{\mu} > 0$$
, $\sum_{i=1}^{\mu} w_i = 1$, $\frac{1}{\sum_{i=1}^{\mu} w_i^2} =: \mu_w \approx \frac{\lambda}{4}$

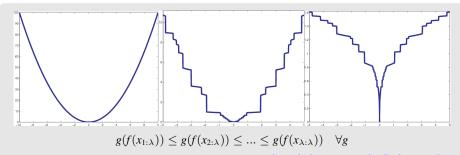

The best μ points are selected from the new solutions (non-elitistic) and weighted intermediate recombination is applied.

Invariance Under Monotonically Increasing Functions

Rank-based algorithms

Update of all parameters uses only the ranks

$$f(x_{1:\lambda}) \le f(x_{2:\lambda}) \le \dots \le f(x_{\lambda:\lambda})$$

g is strictly monotonically increasing g preserves ranks

³Whitley 1989. The GENITOR algorithm and selection pressure: Why rank-based allocation of reproductive trials is best ICGA

Anne Auger & Nikolaus Hansen ()

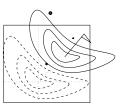

Basic Invariance in Search Space

translation invariance

$$f(x) \leftrightarrow f(x-a)$$

Identical behavior on f and f_a

$$f: \mathbf{x} \mapsto f(\mathbf{x}), \qquad \mathbf{x}^{(t=0)} = \mathbf{x}_0$$

$$f: x \mapsto f(x), \quad x^{(t=0)} = x_0$$

 $f_a: x \mapsto f(x-a), \quad x^{(t=0)} = x_0 + a$

No difference can be observed w.r.t. the argument of *f*

Rotational Invariance in Search Space

• invariance to orthogonal (rigid) transformations ${f R}$, where ${f R}{f R}^T={f I}$ e.g. true for simple evolution strategies recombination operators might jeopardize rotational invariance

Identical behavior on f and $f_{\mathbf{R}}$

$$f: \mathbf{x} \mapsto f(\mathbf{x}), \quad \mathbf{x}^{(t=0)} = \mathbf{x}_0$$

 $f_{\mathbf{R}}: \mathbf{x} \mapsto f(\mathbf{R}\mathbf{x}), \quad \mathbf{x}^{(t=0)} = \mathbf{R}^{-1}(\mathbf{x}_0)$

45

No difference can be observed w.r.t. the argument of f

Invariance

Impact

The grand aim of all science is to cover the greatest number of empirical facts by logical deduction from the smallest number of hypotheses or axioms.

Albert Einstein

- Empirical performance results, for example
 - from benchmark functions
 - from solved real world problems

are only useful if they do generalize to other problems

Invariance is a strong **non-empirical** statement about generalization

generalizing (identical) performance from a single function to a whole class of functions

consequently, invariance is important for the evaluation of search algorithms

$$\sigma \leftarrow \sigma \times \exp\left(\frac{1}{3} \times \frac{p_s - p_{\text{target}}}{1 - p_{\text{target}}}\right) \qquad \text{Increase } \sigma \text{ if } p_s > p_{\text{target}} \\ \text{Decrease } \sigma \text{ if } p_s < p_{\text{target}}$$

$$(1+1)$$
-ES
$$p_{target} = 1/5$$
 IF offspring better parent
$$p_s = 1, \ \sigma \leftarrow \sigma \times \exp(1/3)$$
 ELSE
$$p_s = 0, \ \sigma \leftarrow \sigma / \exp(1/3)^{1/4}$$

Path Length Control (CSA)

The Concept of Cumulative Step-Size Adaptation

$$\begin{array}{rcl} \boldsymbol{x}_i & = & \boldsymbol{m} + \sigma \, \boldsymbol{y}_i \\ \boldsymbol{m} & \leftarrow & \boldsymbol{m} + \sigma \, \boldsymbol{y}_w \end{array}$$

loosely speaking steps are

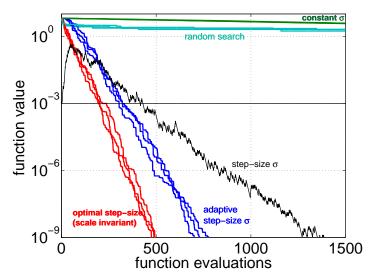

- perpendicular under random selection (in expectation)
- perpendicular in the desired situation (to be most efficient)

Path Length Control (CSA)

The Equations

Initialize $m \in \mathbb{R}^n$, $\sigma \in \mathbb{R}_+$, evolution path $p_{\sigma} = 0$, set $c_{\sigma} \approx 4/n$, $d_{\sigma} \approx 1$.

$$m{m} \leftarrow m{m} + \sigma m{y}_w \quad \text{where } m{y}_w = \sum_{i=1}^{\mu} w_i m{y}_{i:\lambda} \quad \text{update mean}$$
 $m{p}_\sigma \leftarrow (1-c_\sigma) m{p}_\sigma + \sqrt{1-(1-c_\sigma)^2} \quad \sqrt{\mu_w} \quad m{y}_w \quad \text{accounts for } accounts \text{ for } w_i \quad \text{or } c_\sigma \leftarrow \sigma \times \exp\left(\frac{c_\sigma}{d_\sigma} \left(\frac{\|m{p}_\sigma\|}{\mathsf{E}\|\mathcal{N}(\mathbf{0},\mathbf{I})\|} - 1\right)\right) \quad \text{update step-size}$
 $b > 1 \Longleftrightarrow \|m{p}_\sigma\| \text{ is greater than its expectation}$

$$f(\mathbf{x}) = \sum_{i=1}^{n} x_i^2$$

in
$$[-0.2, 0.8]^n$$

for $n = 10$

Evolution Strategies

Recalling

New search points are sampled normally distributed

$$\mathbf{x}_i \sim \mathbf{m} + \sigma \, \mathcal{N}_i(\mathbf{0}, \mathbf{C})$$
 for $i = 1, \dots, \lambda$

as perturbations of m, where $x_i, m \in \mathbb{R}^n$, $\sigma \in \mathbb{R}_+$, $\mathbf{C} \in \mathbb{R}^{n \times n}$

where

- the mean vector $m \in \mathbb{R}^n$ represents the favorite solution
- the so-called step-size $\sigma \in \mathbb{R}_+$ controls the step length
- the covariance matrix $\mathbb{C} \in \mathbb{R}^{n \times n}$ determines the **shape** of the distribution ellipsoid

The remaining question is how to update C.

Covariance Matrix Adaptation

Rank-One Update

$$m \leftarrow m + \sigma y_w, \quad y_w = \sum_{i=1}^{\mu} w_i y_{i:\lambda}, \quad y_i \sim \mathcal{N}_i(\mathbf{0}, \mathbf{C})$$

new distribution,

$$\mathbf{C} \leftarrow 0.8 \times \mathbf{C} + 0.2 \times \mathbf{y}_w \mathbf{y}_w^{\mathrm{T}}$$

the ruling principle: the adaptation increases the likelihood of successful steps, y_w , to appear again

another viewpoint: the adaptation **follows a natural gradient** approximation of the expected fitness

Covariance Matrix Adaptation

Rank-One Update

Initialize $m \in \mathbb{R}^n$, and C = I, set $\sigma = 1$, learning rate $c_{cov} \approx 2/n^2$ While not terminate

$$\begin{aligned} & \boldsymbol{x}_i &= & \boldsymbol{m} + \sigma \, \boldsymbol{y}_i, & \boldsymbol{y}_i &\sim \, \mathcal{N}_i(\boldsymbol{0}, \mathbf{C}) \,, \\ & \boldsymbol{m} &\leftarrow & \boldsymbol{m} + \sigma \boldsymbol{y}_w & \text{where } \boldsymbol{y}_w = \sum_{i=1}^{\mu} w_i \, \boldsymbol{y}_{i:\lambda} \\ & \mathbf{C} &\leftarrow & (1 - c_{\text{cov}}) \mathbf{C} + c_{\text{cov}} \mu_w \, \underbrace{\boldsymbol{y}_w \boldsymbol{y}_w^{\text{T}}}_{\text{rank-one}} & \text{where } \mu_w = \frac{1}{\sum_{i=1}^{\mu} w_i^2} \geq 1 \end{aligned}$$

$\mathbf{C} \leftarrow (1 - c_{\text{cov}})\mathbf{C} + c_{\text{cov}}\mu_{w}\mathbf{v}_{w}\mathbf{v}_{w}^{\mathrm{T}}$

covariance matrix adaptation

- learns all **pairwise dependencies** between variables off-diagonal entries in the covariance matrix reflect the dependencies
- conducts a principle component analysis (PCA) of steps y_w , sequentially in time and space

eigenvectors of the covariance matrix C are the principle components / the principle axes of the mutation ellipsoid, rotational invariant

 learns a new, rotated problem representation and a new metric (Mahalanobis)

components are independent (only) in the new representation rotational invariant

- approximates the inverse Hessian on quadratic functions
 - overwhelming empirical evidence, proof is in progress
- is entirely independent of the given coordinate system

for $\mu = 1$: natural gradient ascent on \mathcal{N}

Cumulation

The Evolution Path

Evolution Path

Conceptually, the evolution path is the search path the strategy takes over a number of generation steps. It can be expressed as a sum of consecutive steps of the mean m.

An exponentially weighted sum of steps y_w is used

$$m{p_c} \propto \sum_{i=0}^g \underbrace{(1-c_c)^{g-i}}_{ ext{exponentially}} m{y}_w^{(i)}$$

The recursive construction of the evolution path (cumulation):

$$p_{\mathrm{c}} \leftarrow \underbrace{(1-c_{\mathrm{c}})}_{\mathrm{decay \ factor}} p_{\mathrm{c}} + \underbrace{\sqrt{1-(1-c_{\mathrm{c}})^2} \sqrt{\mu_{w}}}_{\mathrm{normalization \ factor}} \underbrace{y_{w}}_{\mathrm{input} = \frac{m-m_{\mathrm{old}}}{\sigma}}$$

where $\mu_w = \frac{1}{\sum w_i^2}$, $c_c \ll 1$. History information is accumulated in the evolution path.

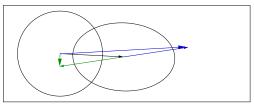

"Cumulation" is a widely used technique and also know as

- exponential smoothing in time series, forecasting
- exponentially weighted mooving average
- iterate averaging in stochastic approximation
- momentum in the back-propagation algorithm for ANNs
- ...

Cumulation

Utilizing the Evolution Path

We used $y_w y_w^T$ for updating C. Because $y_w y_w^T = -y_w (-y_w)^T$ the sign of y_w is lost.

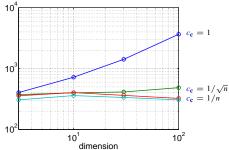

The sign information is (re-)introduced by using the *evolution path*.

where $\mu_{\rm\scriptscriptstyle W}=\frac{1}{\sum w_i^2},\,c_{\rm\scriptscriptstyle C}\ll 1$ such that $1/c_{\rm\scriptscriptstyle C}$ is the "backward time horizon".

Using an **evolution path** for the **rank-one update** of the covariance matrix reduces the number of function evaluations to adapt to a straight ridge from $\mathcal{O}(n^2)$ to $\mathcal{O}(n)$. (a)

Number of f-evaluations divided by dimension on the cigar function

The overall model complexity is n^2 but important parts of the model can be learned in time of order n

^aHansen, Müller and Koumoutsakos 2003. Reducing the Time Complexity of the Derandomized Evolution Strategy with Covariance Matrix Adaptation (CMA-ES), Evolutionary Computation, 11(1), pp. 1-18

Rank- μ Update

$$x_i = m + \sigma y_i, \quad y_i \sim \mathcal{N}_i(\mathbf{0}, \mathbf{C}),$$

 $m \leftarrow m + \sigma y_w \quad y_w = \sum_{i=1}^{\mu} w_i y_{i:\lambda}$

The rank- μ update extends the update rule for **large population sizes** λ using $\mu>1$ vectors to update ${\bf C}$ at each generation step.

The matrix

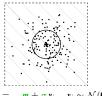

$$\mathbf{C}_{\mu} = \sum_{i=1}^{\mu} w_i \mathbf{y}_{i:\lambda} \mathbf{y}_{i:\lambda}^{\mathrm{T}}$$

computes a weighted mean of the outer products of the best μ steps and has rank $\min(\mu, n)$ with probability one.

The rank- μ update then reads

$$\mathbf{C} \leftarrow (1 - c_{\text{cov}}) \mathbf{C} + c_{\text{cov}} \mathbf{C}_{\mu}$$

where $c_{\text{cov}} \approx \mu_w/n^2$ and $c_{\text{cov}} < 1$.

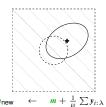

$$x_i = m + \sigma y_i, y_i \sim \mathcal{N}(\mathbf{0}, \mathbb{C})$$

$$\mathbf{C}_{\mu} = \frac{1}{\mu} \sum \mathbf{y}_{i:\lambda} \mathbf{y}_{i:\lambda}^{\mathrm{T}}$$

$$\mathbf{C} \leftarrow (1-1) \times \mathbf{C} + 1 \times \mathbf{C}_{\mu}$$

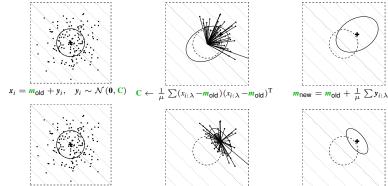

new distribution

sampling of
$$\lambda=150$$
 solutions where $\mathbf{C}=\mathbf{I}$ and $\sigma=1$

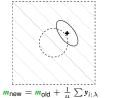

calculating C where
$$\mu=50$$
, $w_1=\cdots=w_\mu=\frac{1}{\mu}$, and $c_{\text{cov}}=1$

Rank- μ CMA versus Estimation of Multivariate Normal Algorithm EMNA_{global} ⁶

rank- μ CMA conducts a PCA of steps

EMNA_{global} conducts a PCA of points

sampling of $\lambda = 150$ solutions (dots)

 $x_i = m_{\text{old}} + y_i, \quad y_i \sim \mathcal{N}(\mathbf{0}, \mathbf{C})$

calculating C from $\mu = 50$ solutions

 $\mathbf{C} \leftarrow \frac{1}{\mu} \sum (x_{i:\lambda} - m_{\text{new}}) (x_{i:\lambda} - m_{\text{new}})^{\mathrm{T}}$

new distribution

The CMA-update yields a larger variance in particular in gradient direction, because m_{new} is the minimizer for the variances when calculating C

Hansen, N. (2006). The CMA Evolution Strategy: A Comparing Review. In J.A. Lozano, P. Larranga, I. Inza and E. Bengoetxea (Eds.). Towards a new evolutionary computation. Advances in estimation of distribution algorithms. pp. 75-102

The rank- μ update

- \bullet increases the possible learning rate in large populations roughly from $2/n^2$ to $\mu_{\scriptscriptstyle W}/n^2$
- can reduce the number of necessary **generations** roughly from $\mathcal{O}(n^2)$ to $\mathcal{O}(n)$ (7)

given
$$\mu_w \propto \lambda \propto n$$

Therefore the rank- μ update is the primary mechanism whenever a large population size is used

say
$$\lambda \ge 3n + 10$$

The rank-one update

• uses the evolution path and reduces the number of necessary function evaluations to learn straight ridges from $\mathcal{O}(n^2)$ to $\mathcal{O}(n)$.

Rank-one update and rank- μ update can be combined

all equations

Summary of Equations

The Covariance Matrix Adaptation Evolution Strategy

Input: $m \in \mathbb{R}^n$, $\sigma \in \mathbb{R}_+$, λ Initialize: C = I, and $p_c = 0$, $p_{\sigma} = 0$,

Set: $c_{\mathbf{c}} \approx 4/n$, $c_{\sigma} \approx 4/n$, $c_{1} \approx 2/n^{2}$, $c_{\mu} \approx \mu_{w}/n^{2}$, $c_{1} + c_{\mu} \leq 1$, $d_{\sigma} \approx 1 + \sqrt{\frac{\mu_{w}}{n}}$,

and $w_{i=1...\lambda}$ such that $\mu_w = \frac{1}{\sum_{i=1}^{\mu} w_i^2} \approx 0.3 \lambda$

While not terminate

$$\begin{aligned} & \boldsymbol{x}_i = \boldsymbol{m} + \sigma \, \boldsymbol{y}_i, \quad \boldsymbol{y}_i \, \sim \, \mathcal{N}_i(\boldsymbol{0}, \mathbf{C}) \,, \quad \text{for } i = 1, \dots, \lambda \\ & \boldsymbol{m} \leftarrow \sum_{i=1}^{\mu} w_i \, \boldsymbol{x}_{i:\lambda} = \boldsymbol{m} + \sigma \, \boldsymbol{y}_w \quad \text{where } \boldsymbol{y}_w = \sum_{i=1}^{\mu} w_i \, \boldsymbol{y}_{i:\lambda} \\ & \boldsymbol{p}_c \leftarrow (1 - c_c) \, \boldsymbol{p}_c + 1\!\!1_{\{\|\boldsymbol{p}_\sigma\| < 1.5\sqrt{n}\}} \sqrt{1 - (1 - c_c)^2} \sqrt{\mu_w} \, \boldsymbol{y}_w \end{aligned} \quad \text{update mean cumulation for } \mathbf{C} \\ & \boldsymbol{p}_\sigma \leftarrow (1 - c_\sigma) \, \boldsymbol{p}_\sigma + \sqrt{1 - (1 - c_\sigma)^2} \sqrt{\mu_w} \, \mathbf{C}^{-\frac{1}{2}} \boldsymbol{y}_w \end{aligned} \quad \text{cumulation for } \boldsymbol{\sigma} \\ & \mathbf{C} \leftarrow (1 - c_1 - c_\mu) \, \mathbf{C} + c_1 \, \boldsymbol{p}_c \, \boldsymbol{p}_c^T + c_\mu \sum_{i=1}^{\mu} w_i \, \boldsymbol{y}_{i:\lambda} \boldsymbol{y}_{i:\lambda}^T \end{aligned} \quad \text{update } \mathbf{C} \\ & \boldsymbol{\sigma} \leftarrow \boldsymbol{\sigma} \times \exp\left(\frac{c_\sigma}{d_\sigma} \left(\frac{\|\boldsymbol{p}_\sigma\|}{\mathbf{E}\|\mathcal{N}(\mathbf{0},\mathbf{D})\|} - 1\right)\right) \end{aligned} \quad \text{update of } \boldsymbol{\sigma}$$

Evolution Strategies in a Nutshell

Sampling from a multi-variate normal distribution

with maximum entropy

- **Rank-based selection**: same performance on g(f(x)) for any g $g: \mathbb{R} \to \mathbb{R}$ strictly monotonic (order preserving)
- **Step-size control**: converge log-linearly on the sphere function and many others possibly with linear scaling in dimension n
- Covariance matrix adaptation: reduce any convex quadratic, g-transformed function

$$f(\mathbf{x}) = g(\mathbf{x}^{\mathrm{T}}\mathbf{H}\mathbf{x})$$

to the sphere function

$$f(\mathbf{x}) = \mathbf{x}^{\mathrm{T}} \mathbf{x}$$

without use of derivatives

lines of equal density align with lines of equal fitness $\mathbb{C} \propto \mathbf{H}^{-1}$

Natural Gradient Descend

• Consider $\arg\min_{\theta} \mathrm{E}(f(x)|\theta)$ under the sampling distribution $p(.|\theta)$ we could improve $\mathrm{E}(f(x)|\theta)$ by following the gradient $\nabla_{\theta}\mathrm{E}(f(x)|\theta)$:

$$\theta \leftarrow \theta - \eta \nabla_{\theta} \mathbf{E}(f(\mathbf{x})|\theta), \qquad \eta > 0$$

 ∇_{θ} depends on the parameterization of the distribution, specifically

Consider the natural gradient of the expected weighted fitness

$$\begin{split} \widetilde{\nabla} \, \mathrm{E}(w_g(f(\boldsymbol{x}))|\theta) &= F_{\theta}^{-1} \nabla_{\theta} \mathrm{E}(w_g(f(\boldsymbol{x}))|\theta) \\ &= \mathrm{E}(w_g(f(\boldsymbol{x})) F_{\theta}^{-1} \nabla_{\theta} \ln p(\boldsymbol{x}|\theta)) \end{split}$$

using the Fisher information matrix $F_{\theta} = \left(\left(\mathbf{E} \frac{\partial^2 \log p(\mathbf{x}|\theta)}{\partial \theta_i \partial \theta_j}\right)\right)_{ij}$ of the density p. The natural gradient is **invariant under re-parameterization** of the distribution.

A Monte-Carlo approximation reads

$$\widetilde{\nabla} \widehat{\mathbf{E}}(\widehat{w}(f(\mathbf{x}))|\theta) = \sum_{i=1}^{\lambda} w_i F_{\theta}^{-1} \nabla_{\theta} \ln p(\mathbf{x}_{i:\lambda}|\theta), \quad w_i = \widehat{w}(f(\mathbf{x}_{i:\lambda})|\theta)$$

CMA-ES = Natural Evolution Strategy + Cumulation

Natural gradient descend using the MC approximation and the normal distribution

Rewriting the update of the distribution mean

$$m_{\mathsf{new}} \leftarrow \sum_{i=1}^{\mu} w_i x_{i:\lambda} = m + \sum_{i=1}^{\mu} w_i (x_{i:\lambda} - m)$$

natural gradient for mean $\frac{\tilde{\partial}}{\tilde{\partial} m} \widehat{E}(w_g(f(x))|m, \mathbb{C})$

Rewriting the update of the covariance matrix⁸

$$\begin{split} \mathbf{C}_{\mathsf{new}} \leftarrow \mathbf{C} + c_1 (\overbrace{\boldsymbol{p_c} \boldsymbol{p_c}^\mathsf{T}}^\mathsf{T} - \mathbf{C}) \\ + \frac{c_\mu}{\sigma^2} \sum_{i=1}^\mu w_i \bigg(\overbrace{(\boldsymbol{x}_{i:\lambda} - \boldsymbol{m}) \left(\boldsymbol{x}_{i:\lambda} - \boldsymbol{m}\right)^\mathsf{T}}^\mathsf{T} - \sigma^2 \mathbf{C} \bigg) \\ & \mathsf{natural gradient for covariance matrix } \frac{\tilde{\varrho}}{\tilde{\varrho} c} \hat{\mathbf{E}}(w_g(f(\boldsymbol{x})) | \boldsymbol{m}, \mathbf{C}) \end{split}$$

Maximum Likelihood Update

The new distribution mean m maximizes the log-likelihood

$$m_{\mathsf{new}} = \arg\max_{m} \sum_{i=1}^{\mu} w_{i} \log p_{\mathcal{N}}(\mathbf{x}_{i:\lambda}|\mathbf{m})$$

independently of the given covariance matrix

The rank- μ update matrix \mathbf{C}_{μ} maximizes the log-likelihood

$$\mathbf{C}_{\mu} = \arg \max_{\mathbf{C}} \sum_{i=1}^{\mu} w_i \log p_{\mathcal{N}} \left(\frac{\mathbf{x}_{i:\lambda} - \mathbf{m}_{\mathsf{old}}}{\sigma} \middle| \mathbf{m}_{\mathsf{old}}, \mathbf{C} \right)$$

 $\log p_{\mathcal{N}}(\mathbf{x}|\mathbf{m}, \mathbf{C}) = -\frac{1}{2} \log \det(2\pi\mathbf{C}) - \frac{1}{2}(\mathbf{x} - \mathbf{m})^{\mathrm{T}}\mathbf{C}^{-1}(\mathbf{x} - \mathbf{m})$ $p_{\mathcal{N}}$ is the density of the multi-variate normal distribution

Variable Metric

On the function class

$$f(\mathbf{x}) = g\left(\frac{1}{2}(\mathbf{x} - \mathbf{x}^*)\mathbf{H}(\mathbf{x} - \mathbf{x}^*)^{\mathrm{T}}\right)$$

the covariance matrix approximates the inverse Hessian up to a constant factor, that is:

$$\mathbb{C} \propto \mathbf{H}^{-1}$$
 (approximately)

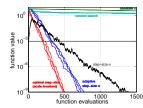

In effect, ellipsoidal level-sets are transformed into spherical level-sets.

 $g:\mathbb{R} \to \mathbb{R}$ is strictly increasing

On Convergence

Evolution Strategies converge with probability one on, e.g., $g\left(\frac{1}{2}x^{T}Hx\right)$ like

$$\|\boldsymbol{m}_k - \boldsymbol{x}^*\| \propto e^{-ck}, \qquad c \leq \frac{0.25}{n}$$

Monte Carlo pure random search converges like

$$\|\mathbf{m}_k - \mathbf{x}^*\| \propto k^{-c} = e^{-c \log k}, \qquad c = \frac{1}{n}$$

Experimentum Crucis (0)

What did we want to achieve?

reduce any convex-quadratic function

$$f(\mathbf{x}) = \mathbf{x}^{\mathrm{T}} \mathbf{H} \mathbf{x}$$

to the sphere model

$$f(\mathbf{x}) = \mathbf{x}^{\mathrm{T}}\mathbf{x}$$

without use of derivatives

e.g. $f(\mathbf{x}) = \sum_{i=1}^{n} 10^{6 \frac{i-1}{n-1}} x_i^2$

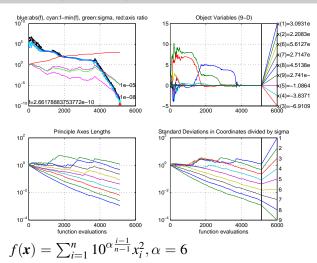

lines of equal density align with lines of equal fitness

$$\mathbf{C} \propto \mathbf{H}^{-1}$$

in a stochastic sense

Experimentum Crucis (1)

The Continuous Search Problem

Difficulties of a non-linear optimization problem are

- dimensionality and non-separabitity
 demands to exploit problem structure, e.g. neighborhood
- ill-conditioning

demands to acquire a second order model

ruggedness

demands a non-local (stochastic? population based?) approach

Main Features of (CMA) Evolution Strategies

- Multivariate normal distribution to generate new search points follows the maximum entropy principle
- 2 Rank-based selection implies invariance, same performance on g(f(x)) for any increasing g more invariance properties are featured
- Step-size control facilitates fast (log-linear) convergence and possibly linear scaling with the dimension based on an evolution path (a non-local trajectory)
- Covariance matrix adaptation (CMA) increases the likelihood of previously successful steps and can improve performance by orders of magnitude

the update follows the natural gradient $\mathbf{C} \propto \mathbf{H}^{-1} \iff$ adapts a variable metric \iff new (rotated) problem representation $\implies f(\mathbf{x}) = g(\mathbf{x}^{\mathrm{T}}\mathbf{H}\mathbf{x})$ reduces to $g(\mathbf{x}^{\mathrm{T}}\mathbf{x})$

Limitations

of CMA Evolution Strategies

- **internal CPU-time**: $10^{-8}n^2$ seconds per function evaluation on a 2GHz PC, tweaks are available 1000 000 f-evaluations in 100-D take 100 seconds *internal* CPU-time
- better methods are presumably available in case of
 - partly separable problems
 - specific problems, for example with cheap gradients

specific methods

• small dimension ($n \ll 10$)

for example Nelder-Mead

• small running times (number of f-evaluations $\ll 100n$)

model-based methods
